PEP Review 2020-07

Green Methanol Production Process

Syed N Naqvi, Executive Director

Abstract

This review presents a techno-economic analysis of a generic green methanol production process. The overall process essentially consists of three different technologies including: (1) CO₂ extraction from atmospheric air; (2) H₂ production from water electrolysis using renewable electricity; and (3) Methanol production using a boiling water-cooled methanol converter. By common definition, the green methanol refers to methanol produced through a production process that emits zero or minimal amount of carbon dioxide (and other greenhouse substances) into the environment during production. Technologies for green methanol production, which have been proposed or are in the emerging stage at the moment, are technically and environmentally different from the modern day, fossil-based methanol technologies that are cheaper to build and operate. But, these technologies can produce 0.5–3.0 ton of CO₂ per ton of methanol, depending on the type of carbon-bearing materials used as fuels and raw materials.

Due to the commercial importance of methanol as a chemical and potential energy source, and in the light of its growing demand resulting from its commercial versatility, concerns about the carbon footprint of the methanol industry are growing—especially regarding the coal-based methanol production processes. An advantage of methanol is that it is a product of CO₂ formed through a reaction of CO₂ with H₂. Hence, methanol is intrinsically a CO₂-neutral material (i.e., it takes one mole of carbon as CO₂ from an outside source in its formation and emits the same into the atmosphere on combustion, or donates its carbon to another material in a chemical reaction). The methanol production process, however, is not carbon neutral on an overall basis as it consumes some form of utilities that are generated from fossil fuels.

Essentially, there are two ways to reduce or eliminate CO₂ emission from a methanol production process; the first way is to use a production technology, which does not utilize an external carbon-bearing source as a carbon donor, or one that would not generate CO₂ as a by-product in the process; the second option is to use carbon-bearing fuel/raw materials and capture/remove CO₂ emitting from the downstream side of process. There is a possibility of a hybrid case also. In this case, the process is based on CO₂ that is extracted partly from the air (instead of from a carbon source like NG, coal, or biomaterial) and partly from the recycled CO₂ generated in the steam production process. This steam is needed for process thermal needs. H₂ is produced from water by an electrolysis process using renewable electricity. Overall, the process is CO₂-negative and extracts a lot more CO₂ from the air than it injects back into the atmosphere.

This review presents a techno-economic evaluation of green methanol process based on the hybrid design.

The analysis of the technology is based on a simulated design of a hypothetical green methanol plant of 150 Mtpd (metric tons per day) capacity. Different aspects of the technology have been analyzed and the analysis results, depending on the feature of technology, are presented in descriptive, tabulated, or diagrammatic formats. Main elements/sections of the technology analysis include: selection and statement of assumptions/bases for process design, process design details (process description with a

complete statement of process operating conditions, material and energy balance, process flow diagram, process discussion, process equipment listing with sizes, utilities summary), and lastly, capital and production economics for three capacity levels—75 Mtpd, 150 Mtpd, and 300 Mtpd.

IHS Markit PEP is of the opinion that, currently, the economics of such a green methanol plant (read details of analysis inside) are not compatible with those of conventional methanol processes. There are, however, certain ways that can make the green process economically closer to the conventional process, in which details about it are described in the review.

Contents

1	Introduction	5
	General background of technologies development	5
	Process options	6
2	Summary	7
	Objective and scope of review	7
	Major design assumptions/Criteria for design	7
	Scope of process economics	8
	Overall economic conclusions	9
	Potential environmental benefit	10
3	Industry status	12
4	Technology	14
	CO ₂ capture from air or flue/industrial waste gases	14
	H ₂ production by water electrolysis	19
	Industrial sizes of electrolyzers	23
5	Process description	25
	Carbon dioxide capture (G-101)	25
	Hydrogen production (G-102)	26
	Methanol production	31
	Methanol process description	34
6	Process discussion	42
	Feedstock	42
	Renewable electric energy	42
	Plant modularization	43
	Miscellaneous plant sections	43
	By-product/s	43
	High recycle rate of process gases	43
	By-product steam	43
	Materials of construction	44
7	Cost estimates	45
	Scope of process economics	45
	Plant economics	45
	Fixed capital costs	46
	Production costs	46
	Overall economic and environmental picture of the process	47
